

Considerable danger of dry and wet avalanches will be encountered in some regions

Edition: 28.3.2018, 17:00 / Next update: 29.3.2018, 08:00

Avalanche danger

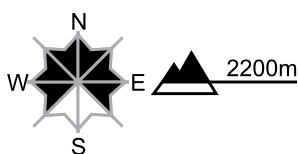

region C

Level 2, moderate

Snow drifts, old snow

Avalanche prone locations

Danger description

Fresh snow drift accumulations are mostly small but can in some cases be released easily. They are to be found in particular adjacent to the ridge line and in gullies and bowls. The number and size of avalanche prone locations will increase with altitude. Avalanches can additionally in isolated cases be released in deeper layers. This applies in particular on very steep north facing slopes in little used backcountry terrain. Such avalanche prone locations are barely recognisable. Careful route selection is important.

Wet avalanches as day progresses, Full-depth avalanches

As a consequence of warming during the day and solar radiation there will be an increase in the danger of wet avalanches to level 3 (considerable). As the day progresses wet avalanches are to be expected, including quite large ones. The avalanche prone locations are to be found in particular on south facing slopes below approximately 2400 m and on north facing slopes below approximately 2000 m. Full-depth avalanches can also occur at any time. Areas with glide cracks are to be avoided as far as possible.
